FREE DVDFab FOR MAC 1.6.3 crack (V6.2.0.6322) serial key. VEU704L BlueChart g2 Vision: VEU704L - France Topo V14.00 (2014.5) The invention relates to a method for conditioning a partially spent electrochemical cell containing lithium in a closed vessel, in which a first electrolyte is applied to the surface of the cathode with a first power supply system and a second electrolyte is applied to the surface of the anode with a second power supply system, in which the anode of the electrochemical cell is connected to the negative pole of the first power supply system and the cathode of the electrochemical cell is connected to the positive pole of the second power supply system. Lithium-based electrochemical cells are extensively used as a source of electrical energy. During a process of charging or discharging the cell, which is referred to as the recharging process, the lithium is reversibly intercalated into the negative electrode in the form of lithium ions (Li^+). The lithium ions (Li^+) are subsequently intercalated from the negative electrode into the intercalation material in the form of lithium ions (Li^-) during the recharging process. The lithium ions (Li^+) are subsequently released from the intercalation material in the form of lithium ions (Li^+) during the discharging process. During the recharging process, the lithium is deposited at the positive electrode in the form of lithium metal. In the process of operating the electrochemical cell, the amount of lithium present in the electrochemical cell decreases by a process of so-called slow dissolution during the charging process and of a process of so-called fast dissolution during the discharging process. The lithium is transferred from the negative electrode to the positive electrode during the charging process and, in the process of operating the electrochemical cell, the lithium is discharged from the positive electrode to the negative electrode during the discharging process. For this purpose, the lithium is transferred from the negative electrode into the anode, wherein the lithium metal contained in the anode oxidizes and the lithium is reduced during the charging process and the lithium metal is oxidized and the lithium is reduced during the discharging process. The anode in the form of lithium metal accumulates over time to the surface of the anode. During the recharging process, the lithium is intercalated from the cathode into the anode during the charging process and the
