The present invention relates to a method of recording and/or reproducing data to and/or from a magneto-optical recording medium, which is applicable to, for example, a magneto-optical disk drive or a magneto-optical memory device and, more particularly, to a magneto-optical recording and/or reproducing method capable of magnetically erasing recorded data with an improved efficiency. As a magneto-optical recording medium, there has conventionally been known a magneto-optical disk having a magnetic layer, which is made of a rare earth metal, a transition metal, and a binder, and which is irradiated with a laser beam to be heated and the coercivity of the magnetic layer is lowered so as to magnetically record data. When data is to be newly recorded, the magneto-optical disk is irradiated with the laser beam, which is modulated in accordance with data to be newly recorded, for recording the data, thereby recording the data as an inverted magnetization. When data is to be reproduced from the magneto-optical disk, the recording state of the inverted magnetization must be recognized based on a detecting signal, which is generated from the magneto-optical disk by the irradiation of the laser beam. Therefore, it is desirable that the magnetization state of the magneto-optical disk is kept in an inverted direction only for a very short time as long as data is not read. For this purpose, conventionally, the laser beam is modulated in accordance with data to be reproduced in advance, and the magnetization of the magneto-optical disk is inverted as a recording pulse by the modulation of the laser beam. However, in such a conventional method in which data is recorded and reproduced based on the inversion of the magnetization of the magnet

The disclosed rolling bearing has an outer ring, an inner ring (inner race) having a tapered raceway surface, and rolling elements (balls) interposed between the outer and inner rings. In this rolling bearing, the inner ring has the raceway surface formed on a tapered raceway surface-forming portion (inner inner ring) that is tapered from an inner end face toward the radially outer side, and a cylindrical raceway surface-forming portion (outer ring) that is formed on the outer circumferential side of the tapered raceway surface-forming portion. The inner inner ring is fitted to the outer ring in such a way as to prevent the inner inner ring from rotating with respect to the outer ring, and an outer peripheral surface of the inner inner ring is radially inwardly deformed into a conical shape. Specifically, the outer peripheral surface of the inner inner ring is formed into a cone shape by being deformed inwardly so that the outer ring can be fit to the inner inner ring with ease. The conical portion of the inner inner ring is formed so as to be tapered from the inner end face toward the radial outer side, and has a circumferential length (depth) in the order of 1.1 to 1.3 times the diameter of the rolling elements. In the above-described rolling bearing, even if an inertial force acting on the rolling element when the rolling element undergoes rolling (rotation) acts on the inner ring, it is possible to prevent a radial component of the inertial force from being transmitted to the outer ring. Thus, it is possible to suppress a load caused by the inertial force from being applied to the inner ring as well as to suppress the inner ring from being eccentrically moved relative to the outer ring. In JP-A-6-60863, in order to enhance a fitting property of the outer ring to the inner inner ring, the rolling bearing is formed to have a tapered raceway surface 570a42141b
