Naloxone is a widely used anti-opioid agent, in part because of the safety profile of subcutaneous administration. Several studies have shown that naloxone suppresses withdrawal symptoms after opioid detoxification. Naloxone is also a specific antagonist for both the μ

and κ opioid receptor subtypes, with equianalgesic doses of naloxone acting as μ - and κ -opioid receptor antagonists. Naloxone is effective at preventing opioid withdrawal in most studies, but only when given at the onset of opioid treatment, thus, it is generally contraindicated during the induction of chronic opioid treatment. We conducted a multicenter, randomized, double-blind, placebo-controlled trial in opioid-dependent patients to determine whether the doses of naloxone that would normally be given as a rescue agent for opiate-associated withdrawal could be substituted for placebo at the initiation of opioid treatment. Fifty-eight opioid-dependent patients were randomized to receive either naloxone or placebo injections. The study demonstrated that when given as rescue for opiate-associated withdrawal, the doses of naloxone routinely used in clinical practice, with a single dose of 2 mg, are not effective in preventing opiate withdrawal.
