Atypical fractures of the tibial plateau treated with plate osteosynthesis. Atypical fractures of the tibial plateau, or clavicular fractures of the tibial plateau, are uncommon injuries that are often misdiagnosed. Due to their high rate of complications and poor prognosis, recognition is crucial. The purpose of this article is to review the literature and describe a case of atypical fracture of the tibial plateau that was successfully treated with plate osteosynthesis. This is a case presentation of an atypical fracture of the tibial plateau and its successful treatment with plate osteosynthesis. The patient was a 38-year-old male who was involved in a motor vehicle accident. The patient had a fracture through the medial one-third of his tibia. He was diagnosed with an atypical fracture of the tibial plateau based on the fracture's appearance on radiographs, and failure to progress through the initial treatment course. Achieving union through the use of an intramedullary rod was not a viable option because of lack of stability. The patient was successfully treated with plate osteosynthesis and serial wound revisions. The patient is currently pain-free with no signs of implant loosening or infection. Plate osteosynthesis may be an effective method to treat atypical fractures of the tibial plateau, particularly those with bone fragment instability and failure of initial treatment. The appropriate treatment option should be selected based on the patient's concerns, history, and fracture pattern. Cite this article: Bone Joint J 2018;100-B:1269-73.
